Introduction. The atmospheric boundary layer (ABL) is the lower part of the atmosphere which is in continuous interaction with the earth's surface due to friction and heating or cooling (Stull, 1988; Garratt, 1992).

boundary layer contains swirls or "eddies." The laminar flow creates less skin friction drag than the turbulent flow, but is less stable. Boundary layer flow over a wing surface begins as a smooth laminar flow.

For large Reynolds numbers ( $R$ ), the decrease of the velocity to zero occurs almost exclusively in a thin layer adjoining the wall. This is called the boundary layer, and it is characterized by the presence of considerable velocity gradients in it. The flow in the boundary layer may be either laminar or turbulent.

Introduction to Boundary Layer: In an ideal fluid shear stresses are totally absent. So when an ideal fluid should flow over a boundary there are no resistances between the boundary and the fluid and the fluid simply slips smoothly over the boundary surface.
